TABLE OF CONTENTS

PREFACE

This format document is submitted as one of the steps in the development of an AN/SQS-23 Sonar Operator Performance Standards Guide under contract N00022-67-C-0172 with the Bureau of Naval Personnel. The intent underlying the submission of this format document is to describe the computation schemes we have developed and the format of the graphs, charts and tables selected to provide the data to be used in the computations. The purpose for such submission is the solicitation of comments and recommendations concerning changes of format which will make the use of the resulting standards either easier or more precise in the shipboard environment.

An indication only of the scope and tenor of the background and descriptive material will be provided in this submission, generally in outline form. Detailed text material will be provided in a later draft submission of the complete Standards Guide. The empirical charts provided are samples only. Complete sets of empirical charts will be provided with the draft submission. The values found in the charts included herein will differ from those submitted with the draft submission. They should not be used for operational evaluation of performance.

The primary purpose for operator standards is to provide the basis for an objective evaluation of operator performance. To insure that such evaluation is independent of the variations due to changes in environment or tactical situation, the effects of these changes must be "normalized" in some manner. The normalization method must be based on data available in the measurement situation (i.e., on board ship). In addition, performance must be measured along dimensions which are operationally significant (e.g., detection range). The cost of naval operations in general, and target services in particular makes it critically important that any method of operator performance evaluation not require the scheduling of additional exercises for its application; the operations and measurements involved must be compatible with exercises conducted for other purposes. Thus, the operator evaluation system must provide additional exploitation of the data already available. The system provided in the proposed standard meets all of the conditions noted above.

The exploitation of already available data clearly will require some additional data manipulation. The principle which has guided us in this effort has been that such manipulation must be of the simplest possible nature consistent with validity of the results. The method devised is believed to be compatible with the computational skills and tools normally found aboard ship.

The data developed to perform the primary function of the guide, namely, evaluation of sonar operator performance, can also provide important tactical data concerning total system performance which includes operator performance in an authoritative manner. It can provide additional guidance in such matters as ASW ship spacing, maximum effective weapon launch range, number of weapons to launch, time to fire, etc. Furthermore, collection of total system and personnel performance data on a fleet-wide basis can provide an important additional data base for use in tactical analyses.

I. INTRODUCTION

A. General

These AN/SQS-23 Sonar Operator Performance Standards have been prepared as one of the tasks under contract N00022-67-C-0172 with the Bureau of Naval Personnel. The scope of this task is to develop performance standards for two key sonar operator functions; namely, submarine detection and target tracking.

The primary purpose of such performance standards is to provide a basis against which to evaluate individual sonar operator performance under the widely varying sonar and tactical conditions encountered at sea, and to do so in terms of the performance to be expected of a "standard operator" under identical conditions. This "standard operator" is one who exhibits normal levels of visual and auditory acuity and response, psychomotor response time and accuracy, and behavioral response to tactical conditions. He also knows and follows the doctrine and procedures prescribed for optimum use of his equipment. This standard sonar operator is neither the "perfect man" nor a "superman"; rather, he should be thought of as an "average trained man." The expected performance of this standard operator is assigned, in these standards, a score of 50 percent. We would expect the performance scores of actual operators, after a statistically valid number of measurements, to average something close to this 50 percent value. No attempt is made to assign a pass or fail score; however, consistently poor performance by an individual should make evident the need for additional training or for tests of sensory capabilities. Conversely, analysis of consistently superior performance by an individual can uncover valid procedural improvements or personnel selection criteria.

B. Applications

At the shipboard command level, use of these standards can give the captain a measure of the tactical capabilities of his sonar system including the operators. It can highlight the need for and urgency of equipment maintenance or operator training. It can assist in the optimum assignment of personnel. It can provide a measure of the expected tactical performance of his sonar system under the existing environmental conditions. Study of the tracking standards can, by supplying data on probable solution accuracy and miss distance, provide a basis for reaching a decision regarding optimum time to fire and number of weapons to fire.

At higher command echelons the Standards Guide can form a basis for the evaluation of the tactical performance of units or for the determination of screen assignments, unit spacing, etc., based on the probable detection performance of units under the existing environmental conditions.

C. Guidelines

Because these performance standards are intended for shipboard use, two sets of guidelines were rigidly followed. First, there is no requirement for data not already available on board ship. Thus, the environmental data required is that regularly logged on board ship. The target data required is that regularly supplied for exercise reconstruction. No data not already available is required. Second, the guidelines used in the development of necessary computation schemes were:

1. All empirical data based on the computer simulation runs are presented in the form of charts or graphs.

2. It is presumed that personnel using this guide can easily perform the arithmetic operations of addition, subtraction, multiplication and short division. Graphical aids (graphs, nomograms, etc.) are provided for other arithmetic operations. The use of a slide rule would normally be faster and more accurate, and hence is recommended in preference to the graphical aids.

3. Tables will be provided for applicable probability functions.

One other guideline was adopted: use of the Standards Guide for the evaluation of operators shall not require additional submarine services, or additional ship operating time. However, some additional manipulation and evaluation of existing data would necessarily be involved.

D. Detection

The concept adopted for evaluation of sonar operator detection performance is that each detection made by an operator whose final classification is "possible submarine" or higher, or which subsequently is determined to have been a submarine upon exercise reconstruction, will be used in his evaluation. This will require the maintenance of a Submarine Detection Log for each operator, this log consisting of a Submarine Detection Data Sheet for each detection of a submarine and a Submarine Detection Summary for each operator. These at-sea detections can and should be supplemented by

detections using PME taped targets under at-sea conditions, so long as the operator is not familiar with the tape used, and the necessary environmental data at time of taping are available. Detections obtained on trainers (e. g., 14A2 series) should not be used.

E. Tracking

The concept chosen for the evaluation of sonar operator tracking performance is different. Each course or speed leg of a submarine during an exercise provides an evaluation of the sonar operator's tracking performance, if the actual course and speed data are made available after the exercise. Thus, a single exercise can give as many evaluations of the operator on the stack as there are course legs. To be completely valid, the target aspect angle should be varied somewhat randomly between bow, beam, quarter aspect, etc. Thus, the sonar operator can and should be evaluated in tracking performance on each submarine exercise. Similarly, PME taped targets can be used provided that actual course and speed data are available and are not preannounced on the tape, and provided that neither the sonar operator nor the attack plotter operator is familiar with the tape. A third method for evaluating sonar operator tracking performance is to use surface targets, provided that the sonar room and UB plot are insulated from data obtained using other sensors. Submarine-like speed ranges should be used by the target surface ship. A fourth method, if the ship is so equipped, is to use controllable artificial targets introduced into the sonar display. A fifth method is to use the data obtained during sessions on the 14A2 training device. No difficulty is envisioned in obtaining sufficient data for the evaluation of sonar operators in tracking performance. The basic fact underlying the entire method of sonar operator evaluation in tracking uncovered in this study, is that a reasonable trained and conscientious attack plotter operator contributes only negligibly to the errors in target course and speed solution. Rather, the levels of the errors in target course and speed solution are almost a direct measure of the accuracy with which the sonar operator positions his cursor in range and bearing.

II. DETECTION STANDARDS

(This section will present a short, relatively non-technical discussion of the basis and assumptions for the standards developed. It will again be emphasized that the selection of the standard chart to be used and the computation of corrections to be applied are based upon data which are already regularly recorded and available on board ship. This will be followed by a concise discussion of the areas of applicability of the detection standards, and a description of the standards documents provided. A lucid description of the use of the standards, "cookbook style" will also be provided. The discussion will follow the outline below.)

A. Technical Basis for the Detection Standards

1. Environmental Factors

   a. Propagation losses
   b. Reverberation computations
   c. Own ship's noise level
   d. Quenching
   e. Sonar source level

2. Operator Performance Factors

   a. Operator visual acuity (normal)

   b. Sonar room lighting level (normally darkened)

   c. Scope brightness and gain adjustment (optimum per environmental results)

   d. Clutter loss (based on reverberation-to-noise ratio)

   e. Semi-random video scan (based on experimental results)

   f. Operator auditory acuity (normal)

   g. Masking effects (noise and reverberation, effects of doppler)

   h. Use of earphones (cuts out ambient noise)

   i. Audio search pattern (normally beam-to-beam)

3. ASW Ship Alert Level

   a. Categorization
   b. Effects

4. Target General Tactical Situation

   a. Approach, screen penetration or attack phases
   b. Evasion phase or ASW freeplay
   c. Effect on data utilization

B. Applicability of the Detection Standards

1. AN/SQS-23 (TRAM Series)

2. Submarine Targets

3. Effect of Target Tactical Situation on Applicability (Initial Detection Versus Reacquisition)

C. Description of the Standards

1. Curves of Probability of Detection Beyond a Given Range (Sample, Figure 1)

2. Curves of Probability of Detection at a Given Range (Sample, Figure 2)

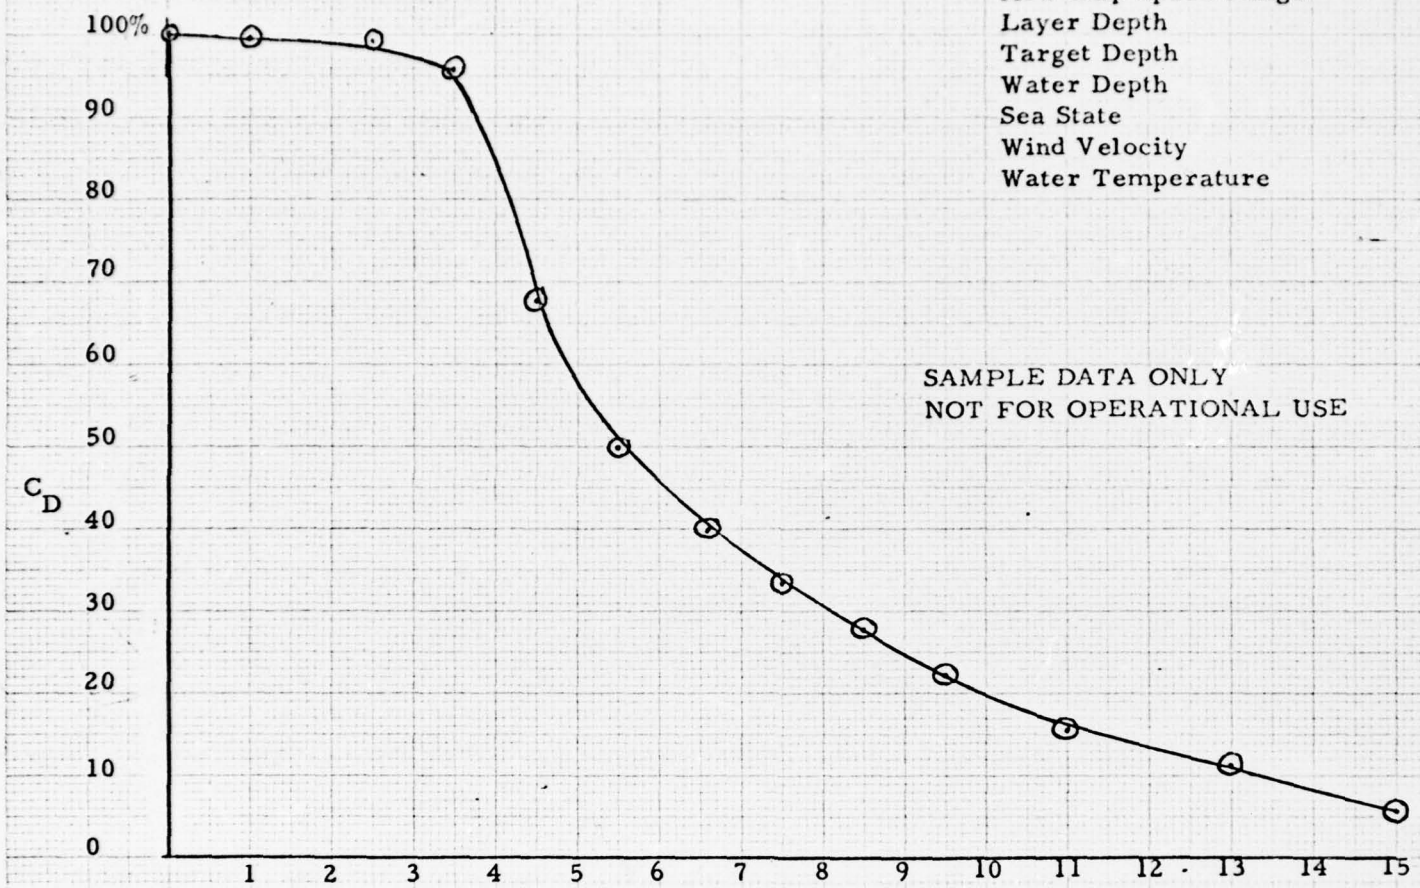
3. Correction Factors for the Following Parameters

   a. ASW alert level
   b. Surface water temperature
   c. Layer depth
   d. Target depth
   e. Wind velocity
   f. Sea state
   g. ASW ship speed
   h. Sonar source level
   i. Audio search sector width

C_D - % of total number of Targets Detected by a given Range

PROBABILITY OF DETECTION BEYOND A GIVEN RANGE

Target Speed Range	3-5 Knots
ASW Ship Speed Range	12-27 Knots
Layer Depth	300 Feet
Target Depth	600 Feet
Water Depth	2,400 Feet
Sea State	2
Wind Velocity	5.0 Knots
Water Temperature	68.0° F



SAMPLE DATA ONLY
NOT FOR OPERATIONAL USE

Figure 1

P_D - % Probability of Detection at a Given Range

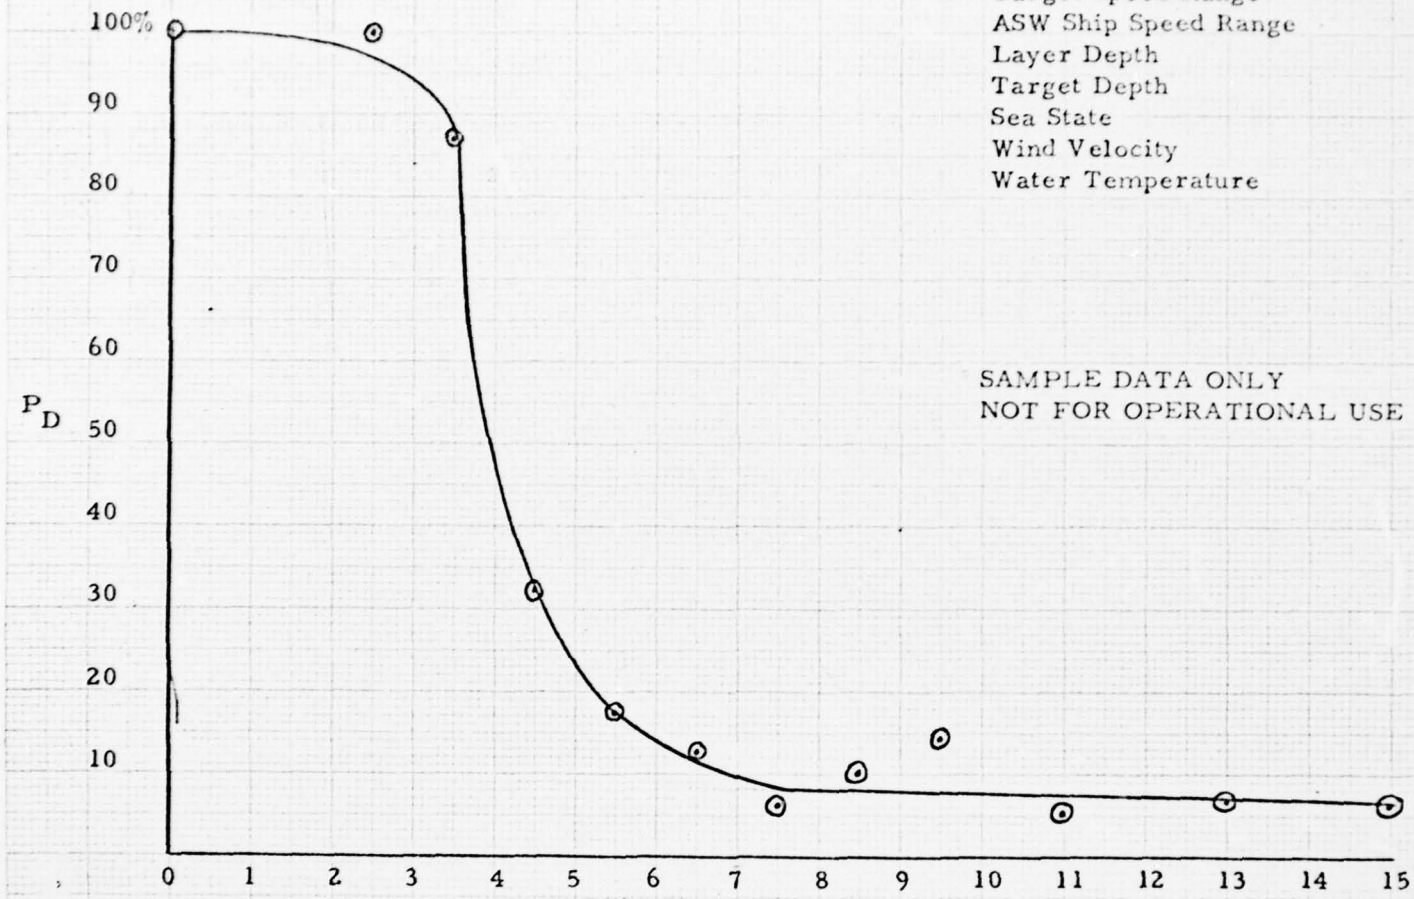


Figure 2

PROBABILITY OF DETECTION
AT A GIVEN RANGE

Target Speed Range	3-15 Knots

Target Depth	600 Feet
Sea State	2
Wind Velocity	5.0 Knots
Water Temperature	68.0° F

SAMPLE DATA ONLY
NOT FOR OPERATIONAL USE

4. Computation and Scoring Sheets

a. Submarine Detection Data Sheet (Figure 3)

b. Sonar Operator Submarine Detection Summary (Figure 4)

c. Sonar Operator Submarine Contact Reacquisition Summary (Figure 5)

D. Use of the Standards

1. Completing the Submarine Detection Data Sheet

a. Completing the data
b. Selecting the appropriate Probability of Detection Chart
c. Computing the detection range corrections

1) Initial detection versus reacquisition or approach versus evasion

2) Environmental conditions

3) Procedure when submarine maneuvers from "below layer" to "in layer" situation

2. Completing the Sonar Operator Submarine Detection Summary

a. Selecting the detections appropriate for entry (initial detections, approach phase detections)

b. Completing the data forms

c. Computing individual detection and cumulative detection scores

d. Maintaining the operator detection performance log

Reacquisition number (N)	Date/Time	Range at which contact was Lost	Reacquisition range	Standard Chart used	Score (S)	Cumulative sum of scores ΣS	Cumulative mean score $\Sigma S/N$	Time between lost contact and reacquisition (min) ΔT	Cumulative reacquisition Time $\Sigma \Delta T$	Mean reacquisition Time (min) $\Sigma \Delta T/N$

Notes: Only reacquisitions of contacts classified possible submarine or higher or which are identified as submarines on exercise reconstruction should be entered in this summary.

Figure 5. Sonar operator submarine detection summary

3. Completing the Sonar Operator Submarine Contact Reacquisition Summary (Optional)

   a. Selecting the detections appropriate for entry (contact reacquisitions, evasion phase)

   b. Completing the individual and cumulative reacquisition performance indices

   c. Validity and usefulness of the contact reacquisition performance indices. (A measure of the reliability in holding contact and speed of reacquisition.)

   d. Mantaining the operator contact reacquisition log

4. Sample Problems

   a. Initial detection

      1) In layer or below layer
      2) Below layer target which maneuvers above layer

   b. Reacquisition

   (The procedure to be followed will be expanded in the Standards Guide. In summary, it is as follows:

   Step 1

   Complete the data entries in the Submarine Detection Data Sheet.

   Step 2

   On the basis of the data, select the appropriate Probability of Detection Curve. Detailed rules will be given in the Guide.

   Step 3

   Compute the detection range corrections to be applied to account for differences of actual environmental and tactical conditions from those used in the selected Probability of Detection Curve.

Step 4

Enter the selected Probability of Detection Curve with the corrected detection range. Read the score.

Step 5

Enter the basic detection data in the Sonar Operator Submarine Detection Summary or the Sonar Operator Submarine Contact Reacquisition Summary as appropriate.

Step 6

Compute the cumulative mean score for the operator.)

III. TRACKING STANDARDS

(This section will present a short, non-technical discussion of the pertinent results and conclusions of the studies report in Dunlap and Associates, Inc., Confidential Report BSD No. 68-509 entitled "Effects of Operator Errors on Accuracy of Target Motion Analysis (U)," Dunlap and Associates, Inc., Confidential Report BSD No. 68-676 entitled "Effects of Exponential Track Smoothing Technique on Accuracy of Target Motion Analysis (U)," and further studies conducted using our tracking simulation model in conjunction with weapons systems simulations. The scope and organization of this discussion will be similar to that used for the detection standards. In addition, there will be some discussion of the tactical implications of the measures and standards presented. The discussion will follow the outline below.)

A. Technical Basis for the Tracking Standards

1. The Validity and Usefulness of Errors in Target Course and Speed Solutions as Measures of Sonar Operator Performance

2. Factors Affecting Error Levels in Target Course and Speed Solution

   a. Target range

   b. Target speed

   c. Time since last change of target course or speed

   d. Equipment errors

   e. Equipment operating modes

   f. Operator precision in positioning his cursor (display dependent)

3. Effects of Various Modes of Equipment Operation

   a. Range scale selection

b. Director mode versus Normal mode

c. Sum Brightening mode versus Difference Brightening mode and the effect of target intermittency

d. Target-centered versus ship-centered display

4. Effect of Ancillary Target Data on the Effectiveness of Tracking

a. Target aspect angle

b. Doppler

c. How accounted for in the scoring (helps his score if it is good)

5. The Technical and Theoretical Basis for the Scoring System

a. Including system bias
b. Eliminating system bias

B. Applicability of the Tracking Standards

1. AN/SQS-23 Sonar Systems

2. Mk 105, Mk 111 and Mk 114 Fire Control Systems

3. Degree of Applicability to other Sonar Systems

a. Equipments using a 7-inch CRT PPI
b. Not to equipments using sector scan indicators

C. Description of the Standards

1. Curves of Target Tracking Course Error (Samples, Figures 6 and 7)

2. Curves of Target Tracking Speed Error (Samples, Figures 8 and 9)

TARGET TRACKING COURSE ERROR

Course Error vs. Tracking Time

Target Speed Range	3-15 knots

4													
5													
6													
7													
8													

Notes
1. A new track leg is started at the start of each change of target course. A new track leg is not started for a speed change alone. Time for each event should be recorded, however.
2. Solution time shall be actual for simulated weapon launch time, if there was a firing during the leg. If there was more than one weapon launch during leg, only the first shall be used. If there was no weapon launch during a leg, the last solution data prior to the start of the next leg shall be used.
3. If there is no speed change during a leg, time since course change will be used in computing the standard speed errc

to submarine attack or lost control
Range at which contact was lost
Reason for termination of encounter

F factors for n > 30 (see note)	0	.25335	.52440	.84162	1.28155	1.64485	2.32635	

Note 1: For values of n greater than 30, table values may be approximated by the formula $(F + \sqrt{2n-1})^2/2$, where F takes on the values shown on the bottom of the table.

Note 2: This table is derived from "Handbook of Mathematical Function, with Formulas, Graphs and Mathematical Tables," edited by M. Abramowitz, and I. A. Stegun, U. S. Department of Commerce, National Bureau of Standards, Applied Mathematics Series 55. Table values were taken from Table 26.8, Percentage Points of the χ^2 Distribution or were interpolated from Table 26.7, Probability Integral of χ^2 Distribution, Incomplete Gamma Function and Cumulative Sums of the Poisson Distribution.

Sonar Operator Tracking Summary
Part I - System Performance

Sonar Operator's Name_____

Exercise Date	Number of Track Legs Evaluated (N)	Exercise System Performance Factor $\left(\sum \frac{E_o}{E_s}\right)$	Scoring Table Entry Number (2N)	Exercise System Performance Score	Cummulative System Performance Factor $\sum\left(\sum \frac{E_o}{E_s}\right)$	Cummulative Scoring Table Entry No. $\sum(2N)$	Cummulative System Performance Score

Figure 12

Sonar Operator Tracking Summary
Part II - Operator Performance
(System Errors - Bias)

Sonar Operator's Name_____

Exercise Date	Number of Track Legs Evaluated (N)	Exercise Operator Performance Factor $\sum\left(\frac{E_o-m}{E_s}\right)$	Exercise Table Entry Number (2N-2)	Exercise Operator Performance Score	Cummulative Operator Performance Factor $\sum\left(\sum\frac{E_o-m}{E_s}\right)$	Cummulative Scoring Table Entry Number (2N-2)	Cummulative Operator Performance Score

Figure 12

d. Computation and scoring

1) Performance on a given leg
2) Performance for the exercise
3) Statistical adequacy of the sample

a) Number of target legs
b) Variations in target aspect

4) Use of E_o/E_s and $(E_o/E_s)^2$ nomograms
5) Use of the scoring tables
6) Eliminating system bias

2. Completing the Sonar Operator Tracking Summary

a. Completing the data

b. Computing the cumulative tracking performance score including system bias

c. Computing the cumulative tracking performance score without system bias

d. Maintaining the operator tracking performance log

3. Sample Problems

(The procedure to be followed will be expanded in the Standards Guide. In summary, it is as follows:

Step 1

Complete the target data entries in the Exercise Tracking Data Sheet, using reconstruction data from the target.

Step 2

Select the appropriate measurement time for each course leg of the target track. Enter target range, estimated target course and estimated target speed.

Step 3

Read the standard course error and standard speed error values for each track leg from the appropriate curves (samples, Figures 6, 7, 8 and 9) using magnitude of last course or speed change, time since last course or speed change, and target range as inputs.

Step 4

Compute the solution course error and solution speed error for each leg at the selected measurement time. Compute the mean course solution error and the mean speed solution error for all track legs in the exercise.

Step 5

Compute the square of the ratio of actual error to standard error $(E_o/E_s)^2$ for the course and for the speed on each track leg using either a slide rule or the nomogram provided (Figure 10). Compute the sum of all these squared ratios.

Step 6

Enter the scoring table (Table I) with the total number of samples used (twice the number of track legs evaluated) and the sum of the squared ratios. Read the score from the column headings, interpolating. This is the tracking performance score for the entire system, including the operator.

Step 7

Compute the square of the ratio of (actual error minus mean error) to (standard error); that is, $(E_o\text{-}m)/E_s$, for course and speed on each track leg as in Step 5. Compute the sum of all these squared ratios.

Step 8

Enter the scoring table (Table I) with two less than the total number of samples used (twice the number of track legs evaluated minus two) and the sum of the squared ratios. Read the score from the column headings, interpolating. This is the tracking

performance score for the sonar operator (system error minus system bias))

E. Tactical Effects of Sonar Operator Tracking Error Levels

1. Splash Point Errors to be Expected with Zero Sonar Operator Tracking Errors

   a. ASROC
   b. DASH

2. Splash Point Errors to be Expected with Standard Sonar Operator Tracking Error Levels

   a. ASROC
   b. DASH

3. Tradeoff Factors in Determining Weapon Launch Time or Need for Multiple Launch

   a. Target range

   b. Tracking time on current target leg

   c. Sonar operator tracking proficiency

   d. Acceptable levels versus expected levels of splash point error
